Hand

A study of a new antithyroidal substance, resorcinol, by means of Iodine-131 (B. Mironov et al., in Univ. Physiol. Inst., Prague). *Fiziol. Radačnice* 3, 327-32 (1954); cf. Bull and Fraser *Lancet* 258, 251 (1950). Resorcinol, a new antithyroidal substance, was studied by means of the ¹³¹I test. Resorcinol blocks binding of ¹³¹I to diiodotyrosine and thyroxine. The level of thyroid hormones dropped by 70%. Resorcinol acts on live thyroid tissue. It inhibits the synthesis of thyroxine and alters the consistency of the colloid of the thyroid gland.

912. ALIMENTARY LIPAEAMIA AND RESISTANCE TO ALTITUDE ANOXIA -
Mosinger B. and Kuhn E. Inst. of Human Nutrit., Prague

NATURE (Lond.) 1957, 180: 4595 (140-141) Graphs 2
Several recent clinical studies having pointed out important relationships between alimentary lipaemia and the function of the circulatory system after a single large fat meal, an experimental study of the effect of alimentary lipaemia upon the resistance of the animal organism to lack of oxygen was undertaken. The experiments were carried out on H-mice of both sexes. Hyperlipaemia was produced by olive oil (0.4 ml./20 g.) given by a metal gastric tube. The difference of mean lethal altitude for the control group and the fat-treated group was highly significant (about 1,500 m.). The average survival time at the altitude of 11,000 m., 4 hr. after consumption of the olive oil, was 133.5 sec., in the control group 245.0 sec. At 10,000 m. the time of survival was 156.0 sec. after the ingestion of fat and 272.8 sec. in the control group.

MOSINGER, B

✓ Relation between activity of digitoxin and some biological factors. B. Mosinger, M. Špačková, and F. Kuffer (Pharm. Control Inst., Prague). Arch. expil. Pathol. Pharmakol. 230, 45-50 (1957).—Young guinea pigs are more resistant against digitoxin than older animals. The value of the lethal dose with reference to body wt. increases the error. The influence of the higher resistance of young animals is eliminated if the dose is referred to body surface. This permits the use of animals of 100-800 g. A. G. M.

791a. THE REACTION OF THE CIRCULATORY SYSTEM TO HYPOXIA IN YOUNG RATS - Moesinger, B., J. Soc. Physiol. Med. Facult. Charles Univ., Plzeň - PHYSIOL BOHEM, 1959, v. 41 (53-62) Graphs 6, Tables 2

The relationship between age, pulse rate and temperature, altitude hypoxia and certain qualitative signs of circulatory insufficiency was studied in young rats aged 1-25 days. The pulse rate did not increase evenly from birth (with a constant environmental temperature), but underwent statistically significant changes between certain consecutive days. Temperature change coincided in time with changes in the pulse rate. The coefficient of correlation between temperature and pulse rate was $r = 0.975$. As distinct from adult rats and other mammals, the young rats reacted to hypoxia corresponding to altitudes of 2,000, 5,000, 7,000, 9,000, 11,000 and 15,000 m. not by an increase in the pulse rate, but by a decrease. The course of the altitude-pulse rate curve was exponential up to a given critical altitude value at which bradycardic collapse occurred. The altitude at which the pulse rate fell to half, and the critical altitude at which collapse occurred, was lowest on the 3rd day after birth.

Abstract : A solution of glucose, galactose and xylose was introduced intraperitoneally to mice and the amount of their unabsorbed residue was determined after 30-60 minutes after the introduction of solutions with concentration of 500 mg%, the speed of absorption (SA) increased considerably in the presence of insulin. After the administration of solutions with 5000 and 1000 mg% of glucose, SA is the same in the presence of insulin as in its absence. -- V.V. Yazvikova

Mosingiewicz, K. Ship Displacement Curve.

"Krzywa wyporności statku". Technika i Gospodarka Morska. No. 12, 1952, pp. 556-561. 1 fig., 7 tabs.

This article deals with the investigation of criterions of applicability of a number of elementary functions suitable for balancing the ship's displacement measurements according to the depth of immersion. The criterions revealed that the displacement curve of the vessel is much steeper than the power and exponential curves. It was, consequently, decided to adopt a type of function which would equal the products of the power function and exponential function, with easily distinguishable criterion of applicability. The correlation of the points of the smaller number of parameters is more accurate than it would be in relation to a 3-nd-power polynomial.

TITLE: A new bench radiation shield

PERIODICAL: Atomnaya energiya, v. 13, no. 3, 1962, 299-300

TEXT: The "Latvenergo" Works have developed a new type of γ -radiation shield 43H (4EN) which can be placed on the working bench and offers protection when handling active substances. Unlike the type 33H (3EN) the bottom plate (18 mm), the front plate (30 mm) and the side plates (18 mm) are made of enamelled steel. Tongs for remote handling, movable in ball-and-socket joints, are fitted into the front. They allow freedom of movement through a solid angle of 75°. Observation is possible through a window of lead glass measuring 210·210 mm². The total weight of the shield is 250 kg (500 kg/m²); it is 750 mm long, 720 mm wide and 700 mm high. The arms are respectively 1000 and 750 mm long, they weigh 0.75 and 0.65 kg and can handle weights of 0.5 and 0.8 kg. There are 2 figures.

TITLE: Photointerferal method for upward scaling of potential fields

SOURCE: AN SSSR. Izvestiya. Fizika zemli, no. 6, 1966, 56-59

TOPIC TAGS: photoelectric cell, cathode

ABSTRACT: Methods for computing potential fields, based on the analogy between the law of change of a potential field in space and the law of change of illumination, are discussed. The author proposes a new variant of the method for upward scaling: the data subject to scaling are converted to light patterns and then a photocell with a spherical cathode is used in making a survey of the scaled field, which is recorded in the form of continuous graphs. Orig. art. has: 2 figures and 4 formulas.

Title : Estuary Irrigation and the Microclimate.
(Limannoye orosheniye i mikroklimat).
Orig Pub : Kukuruz, 1957, No 2, 40-41

Abstract : Corn sowings on non-irrigated plots are compared with those on the large-scale estuary irrigation patches of the Dzerzhinskiy Kolkhoz in Rodinsky Rayon of Altay-skiy Kray. The estuary irrigation creates a more favorable microclimate. When irrigated the Slavgorodskaya Variety 270 yielded 72 centners per hectare of cobs in the milky-waxy ripeness stage and 297 centners per hectare of green stuff, the Odesskaya 10 Variety had correspondingly 67 and 483 centners per hectare, whereas

TITLE:

The Slope Flow at the Priobskoye Plateau (Sklonovyy stok
na Priobskom plato)

PERIODICAL:

Meteorologiya i gidrologiya 1958, Nr 6, pp. 32 - 36 (USSR)

ABSTRACT:

The projecting of shallow water reservoirs (Liman) at the slopes exclusively makes use of the slope flow. The river-bed flow lacks completely. The slope flow is considerably influenced by the distribution of the snow cover. Based on the special characteristics found in relation to this distribution in small catchment areas the measurements of the snow deposits were carried out according to the basic elements of the mentioned plateau (Kulunda steppe), viz. for various periods rich in snow (Ref 6). The calculation showed that the main mass of the snow cover is distributed within the range of the middle part of the slopes (63 - 66 %) which is close to the divide as well as at the upper parts of the slopes (18 - 24 %). They are therefore especially interesting for the Liman irrigation of the meadows and acres in Western Siberia. The coefficients of the slope and river-bed

Card 1/2

The Slope Flow at the Priobskoye Plateau

SU 750-58-6-9/24

flow were investigated in the Rodinskiy district, Altay country in the years 1954 - 1957. Table 1 gives the results of these measurements. The investigations carried out by the author in the Kuznetsk steppe did not prove the statements by other authors according to which the flow takes place within the range of the hydrographic network at a high flow-coefficient, while the coefficient of the slope flow was unimportant (Table 3). The investigations carried out permit the following conclusions: 1) In the years with great water reserves on the surface and great flow losses (1956) relatively small values and coefficients of the slope-and river-bed flow are found. In years with great water reserves on the surface and with relatively great flow losses (1954 and 1957) the greatest differences in the thickness of the layer and in the two mentioned coefficients are noticed. 2) A contour plowing before the winter regulates the slope flow to a higher degree than fallow ground and fields after harvest or with winter corn. There are 4 tables and 9 references, 9 of which are Soviet.

TITLE:

Evaporation From the Surface of the Snow Cover Under the Conditions Prevailing in the Steppe Areas of West Siberia (Ispareniya s poverkhnosti snezhnogo pokrova v usloviyah stepnykh rayonov Zapadnoy Sibiri)

PERIODICAL: Meteorologiya i gidrologiya, 1959, Nr 8, pp 24 - 27 (USSR)

ABSTRACT: Considering the contradictory data of the amount of evaporation from the surface of a snow cover (Refs 10, 3, 4, 5, 9, 12), the results of observations carried out during the melting period by the Gidrologicheskaya ekspeditsiya Zapadno-Sibirskogo filiala AN SSSR (Hydrological Expedition of the West Siberian Branch of the AS USSR) with the participation of the author in spring of 1952 in the area of the reservoir of the Novosibirskaya GES (Novosibirsk Hydroelectric Power Station), and in spring of 1955, 1956, and 1957 in the area of the Kulundinskaya Steppe and Ishimskaya Steppe, are put forward here. The evaporation was determined by exposition of snow samples in vessels with subsequent weighing with an accuracy up to 0.01 g. Cylindrical

Card 1/2

Evaporation From the Surface of the Snow Cover Under
the Conditions Prevailing in the Steppe Areas of West
Siberia

SOV/50-59-8-6/19

vessels with a base of 200 cm², and 5 cm high, were used. At a distance of 1.5 cm from the bottom of the vessel, a net separator was attached for separating the snow from the water during melting. The evaporators were placed so deep into holes that the snow surface in them lay on the same level with the surface of the snow cover. On the basis of the data obtained, the following facts are ascertained: 1) The evaporation from the snow cover under the conditions of West-Siberian steppes is unimportant, and amounts to about 3-5 mm during the whole melting period. 2) In dull weather in spring, there is nearly no evaporation from the surface of the snow cover, since condensation exceeds evaporation in most cases. 3) In fine weather in spring, evaporation prevails at the beginning of the melting period, and condensation at the end of it. There are 2 figures 1 table, and 12 Soviet references.
